

# Blue Eyes

## More Details

Frogs belong to the amphibians (amphi = gr. "on both sides"). Frogs live in their development both in the water and on land. From the eggs hatch the tadpoles, which have a tail and at first no legs. They live in the water. The tadpoles develop into frogs with long, strong hind legs. The transformation into humans happens (unfortunately) only in fairy tales.

"If a frog climbs a ladder in a glass, the weather will be nice." – unfortunately, that's not how a weather forecast works. The idea of the weather frog comes from the fact that our native tree frogs climb leaves and grasses to catch insects in dry weather. In dry weather, insects fly higher than in cold, wet weather. So the most a real tree frog could do in nature is indicate what the weather is like right now. In a jar, of course, this does not work.
